<sup>1</sup>Resident, <sup>2</sup>Associate Professor, Department of General Medicine, Government Medical College and Hospital, Nagpur, Maharashtra, India.

## ABSTRACT

**Objectives:** In patients presenting with acute dyspnoea in the emergency department (ED), the early and correct diagnosis may present a significant clinical challenge. The most common diagnoses of acute shortness of breath and manifesting signs of respiratory distress are decompensated heart failure (HF), pneumonia, chronic obstructive pulmonary disease (COPD), pulmonary embolism (PE), asthma, and acute respiratory distress syndrome (ARDS) and other causes like anaemia. The aim of the study was to measure NT-pro brain natriuretic peptide (BNP) and exhaled end-tidal carbon dioxide (ETCO<sub>2</sub>) in patients presenting with dyspnoea.

**Material and Methods:** This prospective, cross-sectional and observational study was performed at the Government Medical College and Hospital, Nagpur, between October 2019 and October 2021 in patients admitted to the medicine intensive care unit. Three groups of patients were compared: (1) HF-related acute dyspnoea group ( $n = 52$ ), (2) pulmonary (COPD/PE)-related acute dyspnoea group ( $n = 31$ ) and (3) sepsis with ARDS-related dyspnoea group ( $n = 13$ ). All patients underwent initial clinical examination with a recording of initial vital parameters along with on-admission ETCO<sub>2</sub> measurement, NT-proBNP testing, arterial blood gas testing, lung ultrasound examination, 2D echocardiography, chest X-rays, and other basic diagnostic laboratory testing.

**Results:** We included 96 patients during the study period. Median NT-proBNP was found to be maximum for the HF group (11,480 pg/ml) followed by the sepsis group (780 pg/ml) and pulmonary group (231 pg/ml). The mean ETCO<sub>2</sub> value was found to be maximum in the pulmonary group (48.610 mmHg) followed by HF (31.51 mmHg) and the sepsis group (19.46 mmHg). All results were found to be statistically significant ( $P < 0.05$ ).

**Conclusion:** NT-proBNP has high diagnostic accuracy in differentiating acute HF-related dyspnoea from pulmonary (COPD and ARDS)-related acute dyspnoea. The higher levels of ETCO<sub>2</sub> help in diagnosing patients with COPD.

**Keywords:** NT-pro brain natriuretic peptide (NT-Pro BNP), Exhaled end-tidal carbon dioxide (ETCO<sub>2</sub>), Dyspnoea

## INTRODUCTION

Dyspnoea, commonly referred to as shortness of breath, is the subjective sensation of uncomfortable breathing composed of qualitatively distinct sensations that vary in intensity. In patients presenting with acute dyspnoea in a pre-hospital setting, the early and correct diagnosis may present a significant clinical challenge. Epidemiologically, the most common diagnoses among adult patients presenting to an emergency department (ED) with a complaint of acute shortness of breath and manifesting signs of respiratory distress are decompensated heart failure (HF), pneumonia, chronic obstructive pulmonary disease (COPD), pulmonary embolism (PE), asthma, acute respiratory distress syndrome (ARDS) and other causes like anaemia. Differentiating between dyspnoea due to cardiac cause and obstructive airway

disease is an important aspect of patient assessment in the ED.<sup>[1]</sup> It can be differentiated based on various parameters such as clinical history, presentation of the patient, biomarkers, and imaging studies to help appropriately targeted therapy.<sup>[2]</sup> The pre-hospital settings are unlikely to have such diagnostic tests available, so a fast, non-invasive tool is needed to objectively differentiate between these two common causes of dyspnoea. This can be achieved with the use of exhaled end-tidal carbon dioxide (ETCO<sub>2</sub>), a continuous variable that is determined by basal metabolic rate, cardiac output, and ventilation, this can be measured non-invasively by capnography providing valuable information for assessment of the cause of dyspnoea. Obstructive pulmonary disease (COPD/asthma) is characterised in part by hypoventilation, retention of carbon dioxide, and high PaCO<sub>2</sub>, while pulmonary oedema caused by

congestive HF (CHF) is characterised by poor alveolar oxygen exchange and increased ventilation with ETCO<sub>2</sub> levels being significantly lower in the ED patients with CHF as compared to those with obstructive pulmonary disease.<sup>[3,4]</sup> In addition, using an algorithm including ETCO<sub>2</sub> levels in addition to brain natriuretic peptide (BNP) has been shown to improve appropriate diagnosis by physicians in the pre-hospital setting. BNP and aminoterminal pro-BNP (NT-proBNP) have been proposed as early markers of HF and demonstrated to be useful for diagnosing and excluding HF in the ED. A combination of BNP or NT-proBNP testing and standard clinical assessment has been suggested to be superior to either tool used in isolation.

The purpose of this study is to investigate the relative clinical value and role of NT-proBNP and ETCO<sub>2</sub> in the ED to differentiate HF from other causes of acute dyspnoea, especially COPD and sepsis with ARDS. We hypothesise that lower ETCO<sub>2</sub> levels and higher NT-proBNP levels may predict HF versus obstructive pulmonary disease.

### Objectives

The objectives of the study were as follows:

1. To measure NT-proBNP and ETCO<sub>2</sub> in patients presenting with dyspnoea
2. To evaluate the NT-proBNP and ETCO<sub>2</sub> in patients of HF and COPD and other patients presenting with dyspnoea.

### MATERIAL AND METHODS

Our study was a prospective, cross-sectional and observational study and was performed in Government Medical College and Hospital, Nagpur, between October 2019 and October 2021 in patients admitted to medicine intensive care unit and wards. The study was approved by the Institutional Ethical Committee. Informed written consent was taken from all the subjects or their relatives participating in the study.

The patients were further categorised into groups as per their clinical manifestations and investigation reports:

- a. HF ( $n = 52$ )
- b. Pulmonary (COPD – 29 and PE – 2)
- c. Sepsis with ARDS ( $n = 13$ ).

All patients underwent initial clinical examination with a recording of initial vital parameters along with on-admission ETCO<sub>2</sub> measurement, NT-proBNP testing, arterial blood gas (ABG) testing, lung ultrasound examination, 2D echocardiography, chest X-rays, and other basic diagnostic laboratory testing.

### RESULTS

- A total of 96 patients presenting with dyspnoea requiring ventilatory support were included in the study. Of the 96 patients included in the study, 41 were male and 55

**Figure 1:** Lung ultrasound image showing depicting showing comet tail sign (arrows).

were female. The mean age of the patients was  $54.73 \pm 16.71$  years with a minimum age of 21 years and a maximum age of 85 years

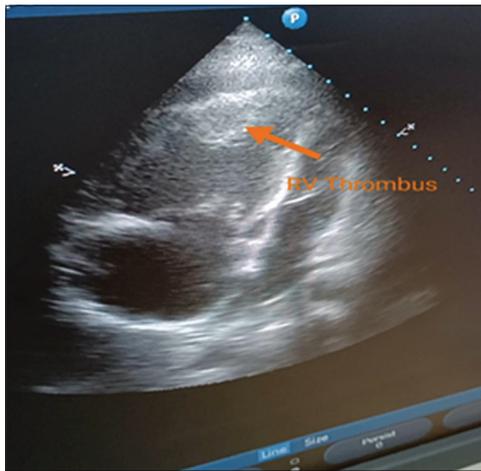

- The HF group consisted of 52 patients (21 M/31 F) (54.2%) with a mean age of  $52 \pm 17.14$  years, the pulmonary group included 31 patients (17 M/14 F) (32.3%) with a mean age of  $61.06 \pm 12.96$  years and the sepsis with ARDS group included 13 patients (3 M/10 F) (13.5%) with a mean age of  $50.54 \pm 19.68$  years
- Systemic hypertension was found to be the most common comorbidity followed by diabetes mellitus, COPD, ischaemic heart disease, valvular heart disease, old pulmonary tuberculosis, and dyslipidaemia. No significant correlation was found between comorbidities and the study results
- [Table 1] showing ABG, P/F ratio, ETCO<sub>2</sub>, and PaCO<sub>2</sub>-ETCO<sub>2</sub> values in all study groups.
- [Table 2] showing electrocardiographic, echocardiographic, and radiographic findings in all the groups [Figures 1 and 2].
- Median NT-proBNP was found to be maximum for the HF group (11,480 pg/ml with an interquartile range of 12,564.75 pg/ml) followed by the sepsis group (780 pg/ml with an interquartile range of 2993.8 pg/ml) followed by the pulmonary group (231 pg/ml with an interquartile range of 216 pg/ml). The group-specific mean NT-proBNP in the HF group was  $13,477.07 \pm 9768.01$  pg/ml followed by  $4890.61 \pm 9583.78$  pg/ml in sepsis with the ARDS group and  $467.10 \pm 798.06$  pg/ml in the pulmonary group. These results were statistically significant ( $P = 0.00$ ). Median NT-proBNP values of all groups were less than mean values due to wide variation between maximum and minimum values of NT-proBNP values in a few patients in all the groups suggestive of outliers in the study groups. This difference in mean and median could be because of the presence of HF in these patients in addition to their primary diagnosis of sepsis/COPD/PE

**Table 1:** ABG, SPO<sub>2</sub>, ETCO<sub>2</sub>, NT-ProBNP in Study Subjects.

| Parameters                           | Heart failure  | Pulmonary  | Sepsis with ARDS  |

**Figure 2:** 2D Echocardiography right ventricle thrombus in pulmonary embolism.

- The mean ETCO<sub>2</sub> was observed to be maximum in the pulmonary group which was 48.61 ± 8.08 mmHg followed by the HF group with a mean ETCO<sub>2</sub> of 31.52 ± 10.92 mmHg and the sepsis with the ARDS group with a mean ETCO<sub>2</sub> of 19.46 ± 12.15 mmHg. This result was statistically significant (P = 0.00)

- The mean PaCO<sub>2</sub>-ETCO<sub>2</sub> was found maximum in the sepsis with the ARDS group as 16.79 ± 6.98 mmHg. The mean PaCO<sub>2</sub>-ETCO<sub>2</sub> in the pulmonary group was 6.43 ± 2.72 mmHg and in the HF group was 5.52 ± 2.07 mmHg (least among all three groups). This result was statistically significant (P = 0.00)
- The study also included two patients with PE with a mean NT-proBNP of 13,649 ± 4240.52 pg/ml, mean ETCO<sub>2</sub> of 29 ± 1.41 mmHg, and mean PaCO<sub>2</sub>-ETCO<sub>2</sub> of 8.8 ± 2.55 mmHg [Table 1]
- According to the above receiver operating characteristic (ROC) curve for NT-proBNP of all groups, the HF group [Figure 3] had the greatest area under the curve (AUC) of 0.944 compared to the pulmonary group [Figure 4] with an AUC of 0.037 and the sepsis group [Figure 5] with AUC of 0.407. Thus, the study showed AUC maximum for HF suggesting NT-proBNP as a better diagnostic marker for HF

While comparing the ROC curve for ETCO<sub>2</sub> of all groups, the pulmonary group [Figure 4] had a maximum AUC of 0.914 as compared to the HF group [Figure 3] with an AUC of 0.318 and the sepsis group [Figure 5] with an AUC of 0.136 (least among all three groups). Thus, indicating

ETCO<sub>2</sub> as a better marker for diagnosing obstructive airway disease

- According to the above ROC curves, the maximum AUC for PaCO<sub>2</sub>-ETCO<sub>2</sub> was found in the sepsis group as 0.972 [Figure 5] as compared to AUC of 0.478 in the pulmonary group [Figure 4] and 0.291 in the HF group [Figure 3], thus indicating PaCO<sub>2</sub>-ETCO<sub>2</sub> as a better marker for the detection of ARDS
- In our study, the correlation between PaCO<sub>2</sub> and ETCO<sub>2</sub> as depicted in [Figure 6] was found to be 0.90, which indicated a strong positive correlation between PaCO<sub>2</sub>

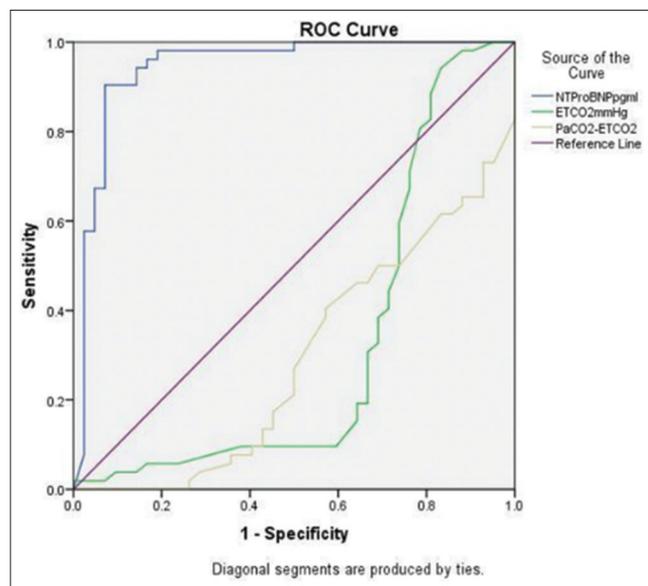

Figure 3: ROC curve for NT-proBNP, ETCO<sub>2</sub> and PaCO<sub>2</sub>-ETCO<sub>2</sub> in the heart failure group.

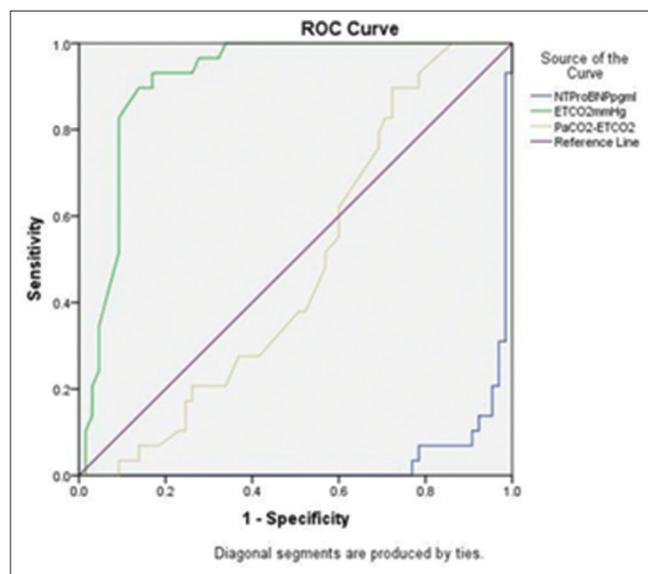

Figure 4: ROC curve for NT-proBNP, ETCO<sub>2</sub> and PaCO<sub>2</sub>-ETCO<sub>2</sub> in the pulmonary group.

and ETCO<sub>2</sub> levels in all patients and was found to be statistically significant ( $P < 0.05$ ). The linear correlation between HCO<sub>3</sub> and ETCO<sub>2</sub> as depicted in [Figure 7] was found as 0.620 which indicated a moderate positive correlation between HCO<sub>3</sub> and ETCO<sub>2</sub> and was found to be statistically significant ( $P < 0.05$ ). The Bland and Altman plot in [Figure 8] showed the limit of the agreement between ETCO<sub>2</sub> and PaCO<sub>2</sub> as 7.92 mmHg and a precision of 6.20 mmHg with 95% C.I. (-4.24, 20.07). Ninety-two (95.83%) of the ETCO<sub>2</sub> measurements were between 95% C.I. which indicates that the values of ETCO<sub>2</sub> could be acceptable for clinical use

- The lung ultrasound used for detecting B lines (comet tail sign) for diagnosis of HF showed

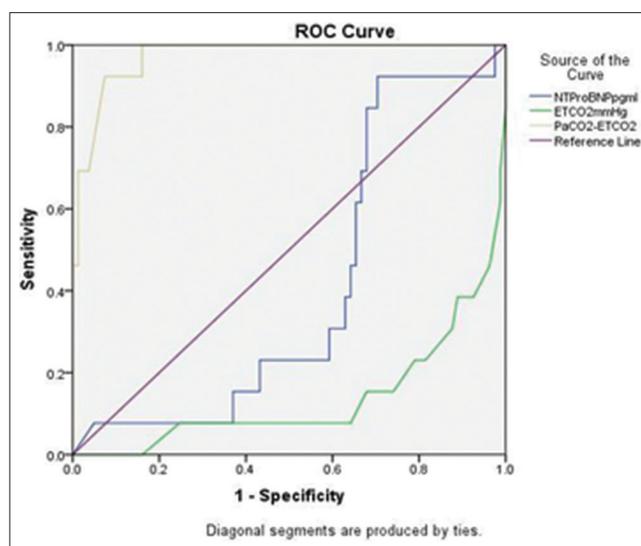

Figure 5: ROC curve for NT-proBNP, ETCO<sub>2</sub> and PaCO<sub>2</sub>-ETCO<sub>2</sub> in the sepsis group.

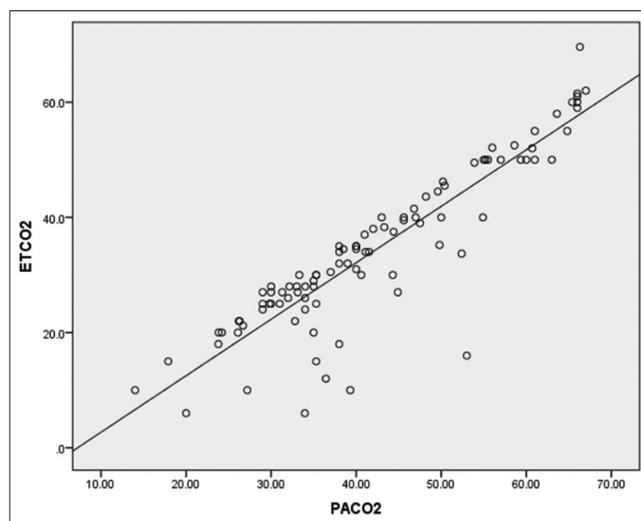

Figure 6: Linear correlation between ETCO<sub>2</sub> and PaCO<sub>2</sub>.

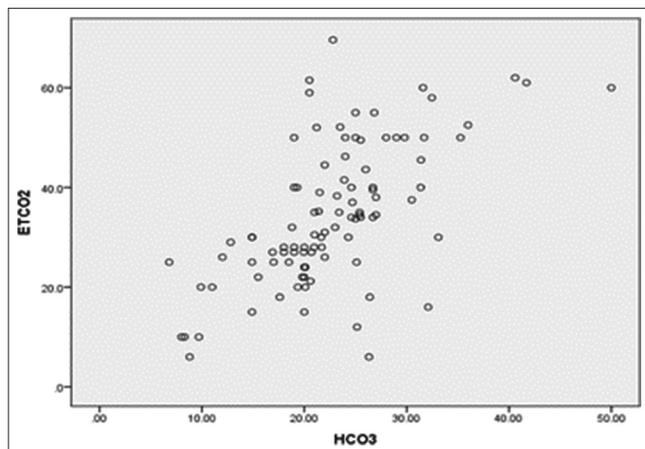

Figure 7: Linear correlation between ETCO<sub>2</sub> and HCO<sub>3</sub>.

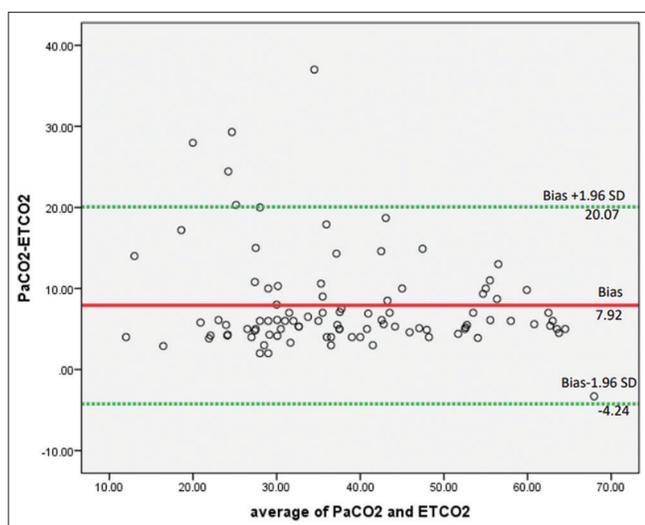

Figure 8: Bland-Altman plot of ETCO<sub>2</sub> compared to PaCO<sub>2</sub>.

sensitivity = 84.62%, specificity = 97.62%, positive predictive value (PPV) = 97.78% and negative predictive value (NPV) = 83.67% with accuracy = 90.43% and likelihood ratio of a positive test as 35.65 [Figure 1 and Table 2]. The NT-proBNP cutoff value was found to be 3942.5 pg/ml along with sensitivity = 90.38%, specificity = 92.86%, PPV = 94% and NPV = 88.63% for NT-proBNP in diagnosis of HF patients. Thus, suggesting that lung ultrasound can be effectively used to exclude HF from pulmonary-related dyspnoeic patients along with positive NT-proBNP results and history of HF.

## DISCUSSION

Our study (similarly to the study by Prosen *et al.*) suggests that NT-proBNP and ultrasound examinations provide diagnostic information useful in the early evaluation of HF in the emergency setting. Prosen *et al.*<sup>[5]</sup> study had mean

NT-proBNP in the HF group as 2263±641.2 pg/ml and that in the pulmonary group was 598.2 ± 361.8 pg/ml with  $P = 0.008$  with AUROC curve for NT-proBNP as 0.90 similar to the results found in our study. Prosen *et al.* study showed 100% sensitivity, 95% specificity, 96% PPV, 100% NPV, and a likelihood ratio of a positive test as 20 for the presence of B lines in lung ultrasound examination for the diagnosis of HF which are near to our study findings. Thus, the combination of ultrasound examination and rapid bedside NT-proBNP testing proves to be a reliable method for the identification of acute HF and its differentiation from COPD/asthma-related causes of acute dyspnoea. Klemen *et al.*<sup>[6]</sup> study had a mean NT-proBNP of 687.2 ± 479.5 pg/ml in the pulmonary-related dyspnoea group and 2756.8 ± 885.3 pg/ml in the acute HF-related dyspnoea group with  $P = 0.004$  suggesting statistically significant importance of NT-proBNP in HF patients. The AUROC curve in this study for NT-proBNP was 0.90 (95% CI 0.85–0.94) which is close to the AUROC curve of our study in the HF group patients. Januzzi *et al.*<sup>[7]</sup> study results showed the median NT-proBNP concentration of patients with acute HF as 2844 pg/ml with an interquartile range of 1247–5976 pg/ml, which was substantially higher than those without acute HF who had a median NT-proBNP value of 98 pg/ml with an interquartile range of 35–369 pg/ml. The ROC curve for all patients demonstrated an AUC of 0.91 (95% CI: 0.90–0.93;  $P < 0.001$ ) which is similar to our study's AUROC value.

This study demonstrates that ETCO<sub>2</sub> levels are lower in patients presenting with dyspnoea caused by HF, as compared with obstructive pulmonary disease. Prior studies such as Klemen *et al.*<sup>[6]</sup> and Hunter *et al.*<sup>[2]</sup> studies have similarly found that ETCO<sub>2</sub> is lower in patients with CHF versus those with obstructive pulmonary disease and have also described using ETCO<sub>2</sub> in conjunction with serum BNP to improve diagnostic accuracy in the pre-hospital setting.

Delorme *et al.*<sup>[8]</sup> study showed that the mean difference between PaCO<sub>2</sub> and ETCO<sub>2</sub> was 8 ± 10 mmHg, and the median value was 6 mmHg (with differences varying from -12 to 41 mmHg). The Bland and Altman plot showed limits of agreement (±1.96 of the difference) of -10 and +26 mmHg, with a mean of +8 mmHg. Using simple linear regression, the correlation between ETCO<sub>2</sub> and PaCO<sub>2</sub> was good ( $R = 0.82$ ). This finding was found to be similar to that observed in our study.

Cinar *et al.*<sup>[9]</sup> study showed that ETCO<sub>2</sub> measurement had a high correlation ( $r = 0.911$ ) and agreement ( $0.5 \pm 5$  mmHg, between -10.5 and +9.5 mmHg) with PaCO<sub>2</sub> levels. The mean ETCO<sub>2</sub> level was 39.47 ± 10.84 mmHg and the mean PaCO<sub>2</sub> level was 38.95 ± 12.27 mmHg. There was a positive, strong and statistically significant correlation between ETCO<sub>2</sub> and PaCO<sub>2</sub> which is similar to our study findings.

Thus, both NT-proBNP and ETCO<sub>2</sub> used together help in the early diagnosis and treatment of HF and respiratory-related dyspnoea, leading to decreased morbidity and mortality in patients presenting with acute dyspnoea.

## CONCLUSION

- NT-proBNP has high diagnostic accuracy in differentiating acute HF-related dyspnoea from pulmonary-related acute dyspnoea
- Lower levels of ETCO<sub>2</sub> were associated with CHF and higher levels of ETCO<sub>2</sub> were observed in patients with respiratory causes of dyspnoea (COPD)
- Higher PaCO<sub>2</sub>-ETCO<sub>2</sub> value was found in patients with sepsis with ARDS and a high correlation was found between PaCO<sub>2</sub> and ETCO<sub>2</sub>. Thus, capnography can be used for primary diagnosis of pulmonary disease patients and patients with metabolic acidosis in emergency wards however, the ABG must be considered the gold standard tool for diagnosis and guiding the treatment
- Ultrasound examination of the lungs alone or in combination with NT-proBNP testing has high diagnostic accuracy in differentiating acute HF related from COPD/ asthma-related causes of acute dyspnoea in emergency settings
- Therefore, both NT-proBNP and ETCO<sub>2</sub> can help in patients presenting with acute dyspnoea for diagnosis and guiding further management.
